

OpenSSL

You have an internal web server and you are concerned about the MITM attack and its consequences. Secure your web server as below:

- 1- Generate a private key(RSA-2048 bits) for your web server.
- 2- Create a “certificate signing request”.
- 3- See the content of .csr file by openssl.
- 4- Create a self-signed certificate by openssl.
- 5- Make a directory in /etc/httpd/ and name it “ssl”. Move the private key and certificate into this directory.
- 6- Configure your web server to run on https and set the keys in its configuration file.
- 7- Restart the web service and check out your configuration that works well.
